Análise dimensional do algoritmo de backtracking

$$\delta^{(4)}_j = a_j - y_j \rightarrow \text{node } j \text{ layer 1}$$

$$\delta^{(2)} = (\theta^{(2)})^T \cdot g^i(z^{(2)})$$

↳ element-wise multiplication

Temos:

9
Entao

(4)
Q4x5000

$$S^{(4)} = \frac{1}{4 \times 5000} a^{(4)} - M^T$$

— # classes

Também temos

Por isso: $(\Theta^{(3)})^T \cdot S^{(4)}$ $\rightarrow M_6^{6 \times 5000}$

E como $g(z^{(3)}) = \frac{1}{1 + e^{-\theta^{(2)} a^{(2)}}}$ não deverá ser per-

Seague grill

$$g'(z^{(3)}) = \frac{d}{dz} g(z^{(3)}) = \frac{d g(\theta^{(2)} a^{(2)})}{d(\theta^{(2)} a^{(2)})} = \frac{-(-1) \cdot e^{-\theta^{(2)}}}{(1 + e^{-\theta^{(2)}} a^{(2)})^2}$$

$$\Rightarrow g'(z^{(3)}) = \frac{1 \cdot e^{-\theta^{(2)}_a z^{(2)}}}{(1 + e^{-\theta^{(2)}_a z^{(2)}})^2} = 4$$

Se desenvolveremos: $a^{(3)} \cdot (1 - a^{(3)})$, lem-

$$\frac{1}{1+e^{-\theta_a^{(2)} \alpha^{(2)}}} \cdot \left(1 - \frac{1}{1+e^{-\theta_a^{(2)} \alpha^{(2)}}} \right) = \frac{1}{1+e^{-\theta_a^{(2)} \alpha^{(2)}}} \cdot \left(\frac{1+e^{-\theta_a^{(2)} \alpha^{(2)}} - 1}{1+e^{-\theta_a^{(2)} \alpha^{(2)}}} \right)$$
